## CSE321 Quiz 2

Marks: 10 Time: 20 min

ID:	Name:	Section:
-----	-------	----------

1. **Define** parallelism and concurrency. Shortly describe their difference. [3]

2. In a high-performance computing environment, a team is optimizing a scientific simulation program used for climate modeling. They have identified a critical computational kernel responsible for solving complex equations that govern atmospheric dynamics. Through profiling, they discover that only 20% of this kernel's execution time is parallelizable, while the remaining 80% must be executed serially due to inherent dependencies in the calculations. If the team manages to enhance the parallelizable portion to run six times faster, calculate the overall speedup they can achieve. [2]

3. The processes below are scheduled using Round Robin scheduling algorithm with time quantum=4. **Draw** the Gantt chart and **calculate** the average turnaround time and average waiting time for each process. [5]

Process ID	Arrival Time	Brust Time
P1	0	6
P2	3	2
P3	4	9
P4	1	5
P5	5	3
